ABSTRACT

Certain aspects of the present disclosure provide a method for wireless communications. The method generally includes allocating resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station and transmitting a control channel indicating the allocated resources to the relay base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link.

DOWNLINK CONTROL CHANNEL FOR RELAY RESOURCE ALLOCATION

CLAIM OF PRIORITY

The present Application for Patent is a continuation of U.S. patent application Ser. No. 12/830,096, filed Jul. 2, 2010, assigned U.S. Pat. No. 8,861,424 with an issue date of Oct. 14, 2014, which claims benefit of U.S. Provisional Patent Application Ser. No. 61/223,331, entitled SYSTEMS AND METHODS OF INTERACTION FOR LTE-A CONTROL DESIGN WITH PDSCH RESOURCE ALLOCATION, filed Jul. 6, 2009, both assigned to the assignee hereof and hereby expressly incorporated by reference herein.

BACKGROUND

Field

Wireless communication systems are widely deployed to provide various types of communication content such as voice, data, and so on. These systems may be multiple-access systems capable of supporting communication with multiple users by sharing the available system resources (e.g., bandwidth and transmit power). Examples of such multiple-access systems include code division multiple access (CDMA) systems, time division multiple access (TDMA) systems, frequency division multiple access (FDMA) systems, 3GPP Long Term Evolution (LTE) systems, and orthogonal frequency division multiple access (OFDMA) systems.

Generally, a wireless multiple-access communication system can simultaneously support communication for multiple wireless terminals. Each terminal communicates with one or more base stations via transmissions on the forward and reverse links. The forward link (or downlink) refers to the communication link from the base stations to the terminals, and the reverse link (or uplink) refers to the communication link from the terminals to the base stations. This communication link may be established via a single-in-single-out, multiple-in-single-out or a multiple-in-multiple-out (MIMO) system.

A MIMO system employs multiple (N_T) transmit antennas and multiple (N_R) receive antennas for data transmission. A MIMO channel formed by the N_T transmit and N_R receive antennas may be decomposed into N_S independent channels, which are also referred to as spatial channels, where $N_S \leq \min\{N_T, N_R\}$. Each of the N_S independent channels corresponds to a dimension. The MIMO system can provide improved performance (e.g., higher throughput and/or greater reliability) if the additional dimensionalities created by the multiple transmit and receive antennas are utilized.

A MIMO system supports a time division duplex (TDD) and frequency division duplex (FDD) systems. In a TDD system, the forward and reverse link transmissions are on the same frequency region so that the reciprocity principle allows the estimation of the forward link channel from the reverse link channel. This enables the access point to extract transmit beamforming gain on the forward link when multiple antennas are available at the access point.

SUMMARY

Certain aspects of the present disclosure provide a method for wireless communications. The method generally includes allocating resources of a backhaul link between a donor base station and a relay base station to the relay station

2

for communicating with the donor base station and transmitting a control channel indicating the allocated resources to the relay base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link.

Certain aspects of the present disclosure provide a method for wireless communications. The method generally includes receiving a control channel indicating allocated resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link and

communicating with the donor base station over the backhaul link using the allocated resources.

Certain aspects of the present disclosure provide an apparatus for wireless communications. The apparatus generally includes means for allocating resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station and means for transmitting a control channel indicating the allocated resources to the relay base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link.

Certain aspects of the present disclosure provide an apparatus for wireless communications. The apparatus generally includes means for receiving a control channel indicating allocated resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link and means for communicating with the donor base station over the backhaul link using the allocated resources.

Certain aspects of the present disclosure provide an apparatus for wireless communications. The apparatus generally includes at least one processor configured to allocate resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, and transmit a control channel indicating the allocated resources to the relay base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link; and a memory coupled with the at least one processor.

Certain aspects of the present disclosure provide an apparatus for wireless communications. The apparatus generally includes at least one processor configured to receive a control channel indicating allocated resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link, and communicate with the donor base station over the backhaul link using the allocated resources; and a memory coupled with the at least one processor.

Certain aspects of the present disclosure provide a computer-program product for wireless communications, the computer-program product comprising a computer-readable medium. The computer-readable medium generally includes code for allocating resources of a backhaul link between a donor base station and a relay base station to the relay station

for communicating with the donor base station and transmitting a control channel indicating the allocated resources to the relay base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link.

Certain aspects of the present disclosure provide a computer-program product for wireless communications, the computer-program product comprising a computer-readable medium. The computer-readable medium generally includes code for receiving a control channel indicating allocated resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link and communicating with the donor base station over the backhaul link using the allocated resources.

BRIEF DESCRIPTION OF THE DRAWINGS

The features, nature, and advantages of the present disclosure will become more apparent from the detailed description set forth below when taken in conjunction with the drawings in which like reference characters identify correspondingly throughout and wherein:

FIG. 1 illustrates a multiple access wireless communication system according to one embodiment.

FIG. 2 is a block diagram of a communication system.

FIG. 3 illustrates an exemplary wireless communications system with a relay base station according to an aspect of the present disclosure.

FIG. 4 illustrates example operations that may be performed by a donor base station according to an aspect of the present disclosure. FIG. 4A illustrates corresponding means-plus-function blocks.

FIG. 5 illustrates example operations that may be performed by a relay base station according to an aspect of the present disclosure. FIG. 5A illustrates corresponding means-plus-function blocks.

FIG. 6 illustrates localized R-PDCCH resources, which are contiguous in frequency.

FIG. 7 illustrates distributed R-PDCCH resources, which are non-contiguous in frequency.

FIG. 8 illustrates an example of distributed R-PDCCH resources, which are non-contiguous in frequency and hop in time within a subframe.

FIG. 9 illustrates an example mapping of logical resource blocks to physical resource blocks, which are non-contiguous in frequency and hop in time within the subframe.

FIG. 10 illustrates an example partitioning of resource block groups into subsets.

FIG. 11 illustrates an example pairing of R-PDCCH resources with PDSCH resources.

DESCRIPTION

The techniques described herein may be used for various wireless communication networks such as Code Division Multiple Access (CDMA) networks, Time Division Multiple Access (TDMA) networks, Frequency Division Multiple Access (FDMA) networks, Orthogonal FDMA (OFDMA) networks, Single-Carrier FDMA (SC-FDMA) networks, etc. The terms “networks” and “systems” are often used interchangeably. A CDMA network may implement a radio technology such as Universal Terrestrial Radio Access

(UTRA), cdma2000, etc. UTRA includes Wideband-CDMA (W-CDMA) and Low Chip Rate (LCR). cdma2000 covers IS-2000, IS-95 and IS-856 standards. A TDMA network may implement a radio technology such as Global System for Mobile Communications (GSM). An OFDMA network may implement a radio technology such as Evolved UTRA (E-UTRA), IEEE 802.11, IEEE 802.16, IEEE 802.20, Flash-OFDM®, etc. UTRA, E-UTRA, and GSM are part of Universal Mobile Telecommunication System (UMTS). Long Term Evolution (LTE) is an upcoming release of UMTS that uses E-UTRA. UTRA, E-UTRA, GSM, UMTS and LTE are described in documents from an organization named “3rd Generation Partnership Project” (3GPP). cdma2000 is described in documents from an organization named “3rd Generation Partnership Project 2” (3GPP2). These various radio technologies and standards are known in the art. For clarity, certain aspects of the techniques are described below for LTE, and LTE terminology is used in much of the description below.

Single carrier frequency division multiple access (SC-FDMA), which utilizes single carrier modulation and frequency domain equalization is a technique. SC-FDMA has similar performance and essentially the same overall complexity as those of OFDMA system. SC-FDMA signal has lower peak-to-average power ratio (PAPR) because of its inherent single carrier structure. SC-FDMA has drawn great attention, especially in the uplink communications where lower PAPR greatly benefits the mobile terminal in terms of transmit power efficiency. It is currently a working assumption for uplink multiple access scheme in 3GPP Long Term Evolution (LTE), or Evolved UTRA.

Referring to FIG. 1, a multiple access wireless communication system according to one embodiment is illustrated. An access point 100 (AP) includes multiple antenna groups, one including 104 and 106, another including 108 and 110, and an additional including 112 and 114. In FIG. 1, only two antennas are shown for each antenna group, however, more or fewer antennas may be utilized for each antenna group. Access terminal 116 (AT) is in communication with antennas 112 and 114, where antennas 112 and 114 transmit information to access terminal 116 over forward link 120 and receive information from access terminal 116 over reverse link 118. Access terminal 122 is in communication with antennas 106 and 108, where antennas 106 and 108 transmit information to access terminal 122 over forward link 126 and receive information from access terminal 122 over reverse link 124. In a FDD system, communication links 118, 120, 124 and 126 may use different frequency for communication. For example, forward link 120 may use a different frequency than that used by reverse link 118.

Each group of antennas and/or the area in which they are designed to communicate is often referred to as a sector of the access point. In the embodiment, antenna groups each are designed to communicate to access terminals in a sector, of the areas covered by access point 100.

In communication over forward links 120 and 126, the transmitting antennas of access point 100 utilize beamforming in order to improve the signal-to-noise ratio of forward links for the different access terminals 116 and 124. Also, an access point using beamforming to transmit to access terminals scattered randomly through its coverage causes less interference to access terminals in neighboring cells than an access point transmitting through a single antenna to all its access terminals.

An access point may be a fixed station used for communicating with the terminals and may also be referred to as an access point, a Node B, or some other terminology. An

5

access terminal may also be called an access terminal, user equipment (UE), a wireless communication device, terminal, access terminal or some other terminology.

FIG. 2 is a block diagram of an embodiment of a transmitter system **210** (also known as the access point) and a receiver system **250** (also known as access terminal) in a MIMO system **200**. At the transmitter system **210**, traffic data for a number of data streams is provided from a data source **212** to a transmit (TX) data processor **214**.

In an embodiment, each data stream is transmitted over a respective transmit antenna. TX data processor **214** formats, codes, and interleaves the traffic data for each data stream based on a particular coding scheme selected for that data stream to provide coded data.

The coded data for each data stream may be multiplexed with pilot data using OFDM techniques. The pilot data is typically a known data pattern that is processed in a known manner and may be used at the receiver system to estimate the channel response. The multiplexed pilot and coded data for each data stream is then modulated (i.e., symbol mapped) based on a particular modulation scheme (e.g., BPSK, QPSK, M-PSK, or M-QAM) selected for that data stream to provide modulation symbols. The data rate, coding, and modulation for each data stream may be determined by instructions performed by processor **230**.

The modulation symbols for all data streams are then provided to a TX MIMO processor **220**, which may further process the modulation symbols (e.g., for OFDM). TX MIMO processor **220** then provides N_T modulation symbol streams to N_T transmitters (TMTR) **222a** through **222t**. In certain embodiments, TX MIMO processor **220** applies beamforming weights to the symbols of the data streams and to the antenna from which the symbol is being transmitted.

Each transmitter **222** receives and processes a respective symbol stream to provide one or more analog signals, and further conditions (e.g., amplifies, filters, and upconverts) the analog signals to provide a modulated signal suitable for transmission over the MIMO channel. N_T modulated signals from transmitters **222a** through **222t** are then transmitted from N_T antennas **224a** through **224t**, respectively.

At receiver system **250**, the transmitted modulated signals are received by N_R antennas **252a** through **252r** and the received signal from each antenna **252** is provided to a respective receiver (RCVR) **254a** through **254r**. Each receiver **254** conditions (e.g., filters, amplifies, and downconverts) a respective received signal, digitizes the conditioned signal to provide samples, and further processes the samples to provide a corresponding "received" symbol stream.

An RX data processor **260** then receives and processes the N_R received symbol streams from N_R receivers **254** based on a particular receiver processing technique to provide N_T "detected" symbol streams. The RX data processor **260** then demodulates, deinterleaves, and decodes each detected symbol stream to recover the traffic data for the data stream. The processing by RX data processor **260** is complementary to that performed by TX MIMO processor **220** and TX data processor **214** at transmitter system **210**.

A processor **270** periodically determines which pre-coding matrix to use (discussed below). Processor **270** formulates a reverse link message comprising a matrix index portion and a rank value portion.

The reverse link message may comprise various types of information regarding the communication link and/or the received data stream. The reverse link message is then processed by a TX data processor **238**, which also receives traffic data for a number of data streams from a data source

6

236, modulated by a modulator **280**, conditioned by transmitters **254a** through **254r**, and transmitted back to transmitter system **210**.

At transmitter system **210**, the modulated signals from receiver system **250** are received by antennas **224**, conditioned by receivers **222**, demodulated by a demodulator **240**, and processed by a RX data processor **242** to extract the reverse link message transmitted by the receiver system **250**. Processor **230** then determines which pre-coding matrix to use for determining the beamforming weights then processes the extracted message.

In an aspect, logical channels are classified into Control Channels and Traffic Channels. Logical Control Channels comprise Broadcast Control Channel (BCCH) which is DL channel for broadcasting system control information. Paging Control Channel (PCCH) which is DL channel that transfers paging information. Multicast Control Channel (MCCH) which is Point-to-multipoint DL channel used for transmitting Multimedia Broadcast and Multicast Service (MBMS) scheduling and control information for one or several MTCHs. Generally, after establishing RRC connection this channel is only used by UEs that receive MBMS (Note: old MCCH+MSCH). Dedicated Control Channel (DCCH) is Point-to-point bi-directional channel that transmits dedicated control information and used by UEs having an RRC connection. In aspect, Logical Traffic Channels comprises a Dedicated Traffic Channel (DTCH) which is Point-to-point bi-directional channel, dedicated to one UE, for the transfer of user information. Also, a Multicast Traffic Channel (MTCH) for Point-to-multipoint DL channel for transmitting traffic data.

In an aspect, Transport Channels are classified into DL and UL. DL Transport Channels comprise a Broadcast Channel (BCH), Downlink Shared Data Channel (DL-SDCH) and a Paging Channel (PCH), the PCH for support of UE power saving (DRX cycle is indicated by the network to the UE), broadcasted over entire cell and mapped to PHY resources which can be used for other control/traffic channels. The UL Transport Channels comprise a Random Access Channel (RACH), a Request Channel (REQCH), a Uplink Shared Data Channel (UL-SDCH) and plurality of PHY channels. The PHY channels comprise a set of DL channels and UL channels.

The DL PHY channels comprise:

- Common Pilot Channel (CPICH)
- Synchronization Channel (SCH)
- Common Control Channel (CCCH)
- Shared DL Control Channel (SDCCH)
- Multicast Control Channel (MCCH)
- Shared UL Assignment Channel (SUACH)
- Acknowledgement Channel (ACKCH)
- DL Physical Shared Data Channel (DL-PSDCH)
- UL Power Control Channel (UPCCH)
- Paging Indicator Channel (PICH)
- Load Indicator Channel (LICH)

The UL PHY Channels comprise:

- Physical Random Access Channel (PRACH)
- Channel Quality Indicator Channel (CQICH)
- Acknowledgement Channel (ACKCH)
- Antenna Subset Indicator Channel (ASICH)
- Shared Request Channel (SREQCH)
- UL Physical Shared Data Channel (UL-PSDCH)
- Broadband Pilot Channel (BPICH)

In an aspect, a channel structure is provided that preserves low PAR (at any given time, the channel is contiguous or uniformly spaced in frequency) properties of a single carrier waveform.

5 AN EXAMPLE RELAY SYSTEM

FIG. 3 illustrates an example wireless system 300 in which certain aspects of the present disclosure may be practiced. As illustrated, the system 300 includes a donor base station (BS) 302 that communicates with a user equipment (UE) 304 via a relay BS 306. The relay base station 306 may communicate with the donor BS 302 via a backhaul link 308 and with the UE 304 via an access link 310.

In other words, the relay base station 306 may receive downlink messages from the donor BS 302 over the backhaul link 308 and relay these messages to the UE 304 over the access link 310. Similarly, the relay BS 306 may receive uplink messages from the UE 304 over the access link 310 and relay these messages to the donor BS 302 over the backhaul link 308.

The relay base station 306 may, thus, be used to supplement a coverage area and help fill "coverage holes." According to certain aspects, a relay BS 306 may appear to a UE 304 as a conventional BS. According to other aspects, certain types of UEs may recognize a relay BS as such, which may enable certain features.

EXAMPLE RELAY PHYSICAL CONTROL CHANNEL DESIGN

Certain aspects of the present disclosure provide techniques for allocating resources of a backhaul link to a relay base station (or relay node B) for use in communicating with a donor base station (or donor node B). According to certain aspects, a relay physical downlink control channel (R-PDCCH) may be transmitted using a subset of physical resource blocks (PRBs) of subframes assigned to the downlink backhaul link. The R-PDCCH may be used to assign downlink resources in the same subframe and/or in one or more later subframes and to assign uplink resources in one or more later subframes.

According to certain aspects, the R-PDCCH, may be used by the donor eNB to dynamically or semi-persistently assign resources for DL as well as UL data (referred to as R-PDSCH and R-PUSCH respectively). Moreover, it may be assumed that R-PDCCH is transmitted on a subset of the OFDM symbols of the subframes assigned for the downlink backhaul link. Such subset of OFDM symbols may include the full set of OFDM symbols available for the backhaul link. Additionally, it may be assumed that the R-PDCCH is transmitted starting from an OFDM symbol within the subframe that is late enough so that the relay can receive it.

Typically, there are several techniques available for multiplexing the R-PDCCH within a DL backhaul subframe, such as frequency division multiplexing (FDM), time division multiplexing (TDM), or a combination thereof. Due to its flexibility, FDM multiplexing may be a desirable technique for multiplexing the R-PDCCH with other traffic on the downlink backhaul link. In general, FDM multiplexing provides the maximum flexibility in terms of scheduling conventional UEs (e.g., Release 8 or "legacy" UEs) in the same subframe together with R-PDCCH, R-PDSCH and PDSCH for more advanced UEs (Release 9 or higher "non-legacy" UEs). FDM multiplexing also allows reuse of dedicated reference signals (DRS) patterns designed for LTE-A in the context of Coordinated Multipoint (CoMP) operation.

FIG. 4 illustrates example operations 400 that may be performed by a donor base station to allocate backhaul resources to a relay station, according to an aspect of the present disclosure.

The operations 400 begin, at 402, by allocating resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station. At 404, the donor BS transmits a control channel (e.g., R-PDCCH) indicating the allocated resources to the relay base station, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link.

FIG. 5 illustrates example operations 500 that may be performed by a relay base station according to an aspect of the present disclosure. In other words, the operations 500 may be performed by a relay BS receiving backhaul resource allocation from a donor BS in accordance with the operations 400.

The operations 500 begin, at 502, by receiving the control channel (e.g., R-PDCCH) indicating allocated resources of the backhaul link, wherein the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link. At 504, the relay BS communicates with the donor BS over the backhaul link using the allocated resources.

Various types of resource allocation may be used to map R-PDCCH to PRBs on the downlink backhaul link. For example, FIG. 6 illustrates an example resource grid 600 where R-PDCCH is mapped to four RBs (R0, RB1, RB2, and RB3) that are contiguous in frequency and do not hop in time, within a subframe, across a slot boundary 602.

As another example, FIG. 7 illustrates an example of distributed resource allocation, with a resource grid 700 where the four RBs are non-contiguous in frequency, but still do not hop in time, within a subframe, across the slot boundary 602. Distributing the PRBs across frequency may help improve frequency diversity. As still another example, FIG. 8 illustrates an example resource grid 800 where the four RBs are non-contiguous in frequency and hop in time within a subframe.

FIG. 9 illustrates distributed resource allocation (e.g., as shown in FIG. 7) in greater detail. As illustrated in the logical resource grid 900, the RBs 902 allocated for R-PDCCH may be contiguous logically, but they may be mapped to PRBs are non-contiguous and hop across the slot boundary within the subframe, as illustrated. As illustrated, certain RBs 908 (illustratively, RB10 and RB11) may not be addressed in distributed resource allocation for a physical shared data channel of a UE. According to certain aspects, a location of the RBs for the control channel may be centered around these RBs.

As illustrated in FIG. 9, there may be a gap value N_{gap} . As shown in Table 1-1 below, a single gap value may be defined for small system bandwidths, and two for large bandwidths:

TABLE 1-1

RB gap values		
System BW (N_{RB}^{DL})	Gap (N_{gap})	
	1 st Gap ($N_{gap, 1}$)	2 nd Gap ($N_{gap, 2}$)
6-10	$\lceil N_{RB}^{DL}/2 \rceil$	N/A
11	4	N/A
12-19	8	N/A

TABLE 1-1-continued

RB gap values		
System BW (N_{RB}^{DL})	Gap (N_{gap})	
	1 st Gap ($N_{gap, 1}$)	2 nd Gap ($N_{gap, 2}$)
20-26	12	N/A
27-44	18	N/A
45-49	27	N/A
50-63	27	9
64-79	32	16
80-110	48	16

In the example of FIG. 9, there are 22 RBs, thus a single gap is 12 ($N_{gap}=12$). The selection of the gap value in case of large system bandwidth is typically done a per UE basis, and in a dynamic manner (indicated using 1-bit in DCI format 1A/1B/1D).

The location and the sizes of the R-PDCCH may be pre-configured or broadcasted. According to certain aspects, PRBs allocated for R-PDCCH may be signaled via a bitmap, for example, with a one-to-one mapping or some other approach. As illustrated in FIG. 10, with a first approach, a bitmap may indicate which resource block groups 1010 (RBG1-RBG17) and/or RBs within each group are allocated for R-PDCCH. Thus, a single bit may be required for each RBG or RB, which may be relatively expensive, in terms of signaling overhead. In the second approach, RBGs may be divided into subsets. In the illustrated example, RBG1-RBG17 are divided into subset 1002 with RBG1, RBG4 . . . RBG15, subset 1004 with RBG2, RBG5, . . . RBG16, and subset 1006 with RBG3, RBG6, . . . RBG17. Two bits may be used to indicate one of the subsets, while another set of bits may be used to indicate which RBGs within the subset are allocated for R-PDCCH.

A general design decision is how to select the size and (optionally, the hopping) of R-PDCCH such that the design has minimal impact on PDSCH resource allocation. As shown in Table 1-2 below, RB group size may also depend on system bandwidth:

TABLE 1-2

System Bandwidth N_{RB}^{DL}	RBG Size (P)
≤ 10	1
11-26	2
27-63	3
64-110	4

According to certain aspects, a size of R-PDCCH may be aligned with a bandwidth-dependent resource block group (RBG) size. As an example, for a 20 MHz, RBG size is 2 and, thus, the size of R-PDCCH resource may be integer multiples of 2 RBs (e.g., 4RBs or 2 RBs for finer granularity). A larger granularity may result in wasted RBs, while a finer granularity may result in an increase in signaling overhead to indicate the locations of more groups of RBs.

As noted above, for localized R-PDCCH resource allocation (as shown in FIG. 6), the location of R-PDCCH can be centered around the RBs which may not be addressed (e.g., RBs 10 and 11 as shown in FIG. 9).

For distributed R-PDCCH resource allocation (as shown in FIGS. 7 and 8), the “gap” in the non-contiguous R-PDCCH resource location may be aligned with the gap defined for PDSCH. As noted above, there are two gaps values for large system bandwidth. In this case, the “gap” for R-PDCCH may be aligned with one of the gap values for PDSCH

11

(e.g., the first one). 1. According to certain aspects, the R-PDCCH resource size may be selected considering other principles in DVRB design. As an example, if the diversity level in PDSCH DVRB is four, the gap and the granularity of R-PDCCH resource may be determined taking this into account, for example, using the same gap as in PDSCH and in multiples of 4 RBs, regardless (independent) of system bandwidth.

For R-PDCCH resource allocation with PRBs that are non-contiguous in frequency and with hops across slot boundaries (as illustrated in FIG. 8), R-PDCCH location considerations as above may be taken into account. Regarding R-PDCCH resource size granularity, this may be a fraction of 4 RBs (e.g., 2 RBs, or 1 RB), such that an R-PDCCH can pair with a DVRB PDSCH assignment. As an example, as illustrated in FIG. 11, 2 RBs of R-PDCCH may be paired with another 2 RBs for PDSCH transmission (e.g., RB0 and RB1 for R-PDCCH, RB2 and RB3 for PDSCH). While illustrated as logically contiguous, RB0-RB3 may be non-contiguous in frequency and hop across slot boundaries (as shown in FIG. 8).

The various operations of methods described above may be performed by any suitable means capable of performing the corresponding functions. The means may include various hardware and/or software component(s) and/or module(s), including, but not limited to a circuit, an application specific integrated circuit (ASIC), or processor. Generally, where there are operations illustrated in Figures, those operations may have corresponding counterpart means-plus-function components with similar numbering. For example, blocks 400 and 500 illustrated in FIGS. 4 and 5 correspond to means-plus-function blocks 400A and 500A illustrated in FIGS. 4A and 5A.

It is understood that the specific order or hierarchy of steps in the processes disclosed is an example of exemplary approaches. Based upon design preferences, it is understood that the specific order or hierarchy of steps in the processes may be rearranged while remaining within the scope of the present disclosure. The accompanying method claims present elements of the various steps in a sample order, and are not meant to be limited to the specific order or hierarchy presented.

Those of skill in the art would understand that information and signals may be represented using any of a variety of different technologies and techniques. For example, data, instructions, commands, information, signals, bits, symbols and chips that may be referenced throughout the above description may be represented by voltages, currents, electromagnetic waves, magnetic fields or particles, optical fields or particles, or any combination thereof.

Those of skill would further appreciate that the various illustrative logical blocks, modules, circuits, and algorithm steps described in connection with the embodiments disclosed herein may be implemented as electronic hardware, computer software, or combinations of both. To clearly illustrate this interchangeability of hardware and software, various illustrative components, blocks, modules, circuits, and steps have been described above generally in terms of their functionality. Whether such functionality is implemented as hardware or software depends upon the particular application and design constraints imposed on the overall system. Skilled artisans may implement the described functionality in varying ways for each particular application, but such implementation decisions should not be interpreted as causing a departure from the scope of the present disclosure.

The various illustrative logical blocks, modules, and circuits described in connection with the embodiments dis-

12

closed herein may be implemented or performed with a general purpose processor, a digital signal processor (DSP), an application specific integrated circuit (ASIC), a field programmable gate array (FPGA) or other programmable logic device, discrete gate or transistor logic, discrete hardware components, or any combination thereof designed to perform the functions described herein. A general purpose processor may be a microprocessor, but in the alternative, the processor may be any conventional processor, controller, microcontroller, or state machine. A processor may also be implemented as a combination of computing devices, e.g., a combination of a DSP and a microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

The steps of a method or algorithm described in connection with the embodiments disclosed herein may be embodied directly in hardware, in a software module executed by a processor, or in a combination of the two. A software module may reside in RAM memory, flash memory, ROM memory, EPROM memory, EEPROM memory, registers, hard disk, a removable disk, a CD-ROM, or any other form of storage medium known in the art. An exemplary storage medium is coupled to the processor such the processor can read information from, and write information to, the storage medium. In the alternative, the storage medium may be integral to the processor. The processor and the storage medium may reside in an ASIC. The ASIC may reside in a user terminal. In the alternative, the processor and the storage medium may reside as discrete components in a user terminal.

The previous description of the disclosed embodiments is provided to enable any person skilled in the art to make or use the present disclosure. Various modifications to these embodiments will be readily apparent to those skilled in the art, and the generic principles defined herein may be applied to other embodiments without departing from the spirit or scope of the disclosure. Thus, the present disclosure is not intended to be limited to the embodiments shown herein but is to be accorded the widest scope consistent with the principles and novel features disclosed herein.

What is claimed is:

1. A method for wireless communications, comprising:
 - allocating resources of a backhaul link between a donor base station and a relay base station to the relay base station for communicating with the donor base station; and
 - transmitting signaling on a control channel indicating the allocated resources to the relay base station, wherein the signaling on the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link, and wherein the control channel is mapped to the subset of PRBs based on a resource allocation type for downlink communications on the backhaul link.
2. The method of claim 1, wherein the signaling on the control channel is transmitted on PRBs that are contiguous in frequency and do not hop in time within a subframe.
3. The method of claim 1, wherein a location of the control channel is centered around resource blocks that are not used in distributed resource allocation of resource blocks for a physical shared data channel of a user equipment (UE).
4. The method of claim 1, wherein the signaling on the control channel is transmitted on PRBs that are non-contiguous in frequency and do not hop in time within a subframe.

13

5. The method of claim 4, wherein a gap in the non-contiguous PRBs is aligned with a defined gap in resource blocks defined for a physical shared data channel of a user equipment (UE).

6. The method of claim 4, wherein a size of the control channel has a granularity of N resource blocks (RBs), wherein N is independent of system bandwidth.

7. The method of claim 1, wherein the signaling on the control channel is transmitted on PRBs that are non-contiguous in frequency and hop in time within a subframe.

8. The method of claim 7, wherein:

a size of the control channel has a granularity of N resource blocks (RBs), wherein N is a fraction of a bandwidth-dependent resource block group (RBG) size; and

one or more RBs of the control channel are transmitted with one or more RBs of a physical shared data channel of a user equipment (UE) within the same RBG.

9. The method of claim 1, further comprising transmitting a set of bits indicating locations of the PRBs.

10. The method of claim 1, wherein the control channel comprises a physical downlink control channel (PDCCH).

11. The method of claim 1, wherein the resources are allocated for at least one of a physical downlink shared channel or a physical uplink shared channel.

12. The method of claim 1, wherein a resource block group size is an integer multiple of 2 resource blocks.

13. A method for wireless communications, comprising:

receiving signaling on a control channel indicating allocated resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, wherein the signaling on the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link, and wherein the control channel is mapped to the subset of PRBs based on a resource allocation type for downlink communications on the backhaul link; and

communicating with the donor base station over the backhaul link using the allocated resources.

14. The method of claim 13, wherein the signaling on the control channel is transmitted on PRBs that are contiguous in frequency and do not hop in time within a subframe.

15. The method of claim 13, wherein a location of the control channel is centered around resource blocks that are not used in distributed resource allocation of resource blocks for a physical shared data channel of a user equipment (UE).

16. The method of claim 13, wherein the signaling on the control channel is transmitted on PRBs that are non-contiguous in frequency and do not hop in time within a subframe.

14

17. The method of claim 16, wherein a gap in the non-contiguous PRBs is aligned with a defined gap in resource blocks defined for a physical shared data channel of a user equipment (UE).

18. The method of claim 16, wherein a size of the control channel has a granularity of N resource blocks (RBs), wherein N is independent of system bandwidth.

19. The method of claim 13, wherein the signaling on the control channel is transmitted on PRBs that are non-contiguous in frequency and hop in time within a subframe.

20. The method of claim 19, wherein:

a size of the control channel has a granularity of N resource blocks (RBs), wherein N is a fraction of a bandwidth-dependent resource block group (RBG) size; and

one or more RBs of the control channel are transmitted with one or more RBs of a physical shared data channel of a user equipment (UE) within the same RBG.

21. The method of claim 13, further comprising receiving a set of bits indicating locations of the PRBs.

22. An apparatus for wireless communications, comprising:

at least one processor configured to:

allocate resources of a backhaul link between a donor base station and a relay base station to the relay base station for communicating with the donor base station; and

transmit signaling on a control channel indicating the allocated resources to the relay base station, wherein the signaling on the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link, and wherein the control channel is mapped to the subset of PRBs based on a resource allocation type for downlink communications on the backhaul link; and

a memory coupled with the at least one processor.

23. An apparatus for wireless communications, comprising:

at least one processor configured to:

receive signaling on a control channel indicating allocated resources of a backhaul link between a donor base station and a relay base station to the relay station for communicating with the donor base station, wherein the signaling on the control channel is transmitted on a subset of physical resource blocks (PRBs) of subframes assigned for downlink communications on the backhaul link, and wherein the control channel is mapped to the subset of PRBs on a resource allocation type for downlink communications on the backhaul link; and

communicate with the donor base station over the backhaul link using the allocated resources; and a memory coupled with the at least one processor.
